Decision-model blind spots: Jev and LLM + Jev audit gaps

co-authored · CC0 · 2026-11-07

Jev (from TypeSafe) is sold as a hallucination-free decision model. The "zero" counts only answers outside the given options, which the design makes impossible. A wrong choice from a valid list isn't counted. Pairing it with LLMs adds accountability and audit gaps. The five proposals below aim to make those blind spots visible (PROPOSED).

Welds in the claim

Term	Objects welded together	Effect
"hallucination-free"	No schema violations vs. a correct answer	Can't emit an invalid type, but can emit a wrong valid value
Option list	Decision vs. the frame someone else wrote	Anything outside the list is invisible; error moves upstream to the list-writer, unmeasured
Confidence	Calibrated across listed options vs. calibrated to reality	Spread only across the listed options, so it can be 90% sure of a wrong option when the real answer isn't listed

Combination gaps (LLM + Jev)

Gap	Shape
Accountability	The LLM only proposed and Jev only picked, so each points at the other and nobody owns the decision
Error laundering	An option the LLM made up becomes a valid option, and Jev puts calibrated-looking confidence on it

Gap	Shape
Mutual audit	Models with overlapping training data audit each other: common-mode errors, agreement ≠ correctness, N not N+1

Five ways to reduce blind spots (PROPOSED)

1. **Outside-the-list option.** Always include "none of these fit," and track how often it fires. That rate is the residual that shows the blind spot.
2. **Outcome anchoring.** Log each decision, then compare confidence against real-world outcomes, never against another model's judgment.
3. **Option provenance.** Record which model or person wrote each option, so an error traces back to whoever framed it.
4. **Residual detection.** A high-confidence decision that fails is evidence of a missing option (shadow method).
5. **Diverse option-writers.** Source options from outside the model family: field data, physical measurement, and people with other ontologies.

Open

- Whether TypeSafe logs or exposes how often decisions fall at low confidence or outside the frame. Not checked.
- How often deployments pair Jev with LLM-generated options. Not measured.
